# 5-Alkenylthiazoles as In-Out Dienes in Polar [4+2] Cycloaddition Reactions 

Mateo Alajarin, ${ }^{*[a]}$ Jose Cabrera, ${ }^{[a]}$ Pilar Sanchez-Andrada, ${ }^{[a, b]}$ Delia Bautista ${ }^{[c]}$ and Aurelia Pastor* ${ }^{[a]}$

Keywords: Cycloaddition / Nitrogen heterocycles / Cyclization / Zwitterions / Reaction mechanisms

5-Alkenyl-2-aminothiazoles react as in-out dienes with a wide range of electron-poor dienophiles leading to the corresponding cycloaddition products in good to excellent yields. The [4+2] cycloadditions of 5-alkenyl-2-aminothiazoles can be classified as site-selective since only the diene moiety including the formal C-C double bond of the heterocycle and that of the sidechain is involved. Calculations of the HOMO energy values of representative 5-alkenyl-2-aminothiazoles are disclosed.

#### Abstract

The cycloadditions are endo-selective with $N$ phenylmaleimide or maleic anhydride and regioselective when the reactions are conducted with non symmetrical dienophiles. Completely oxidized cycloadducts are obtained in the reactions of 5-alkenyl-2-aminothiazoles with naphthoquinone or DMAD. Unexpectedly, the reactions with PTAD are not stereospecific. A mechanism placed at the concerted/stepwise boundary is proposed.

## Introduction

The 1,3-thiazole ring plays an important role in nature and it is present in a high number of molecules with powerful biological activities. ${ }^{[1]}$ For instance, thiazolo[5,4-b]pyridin-5(4H)-one derivatives are efficient HIV integrase strand transfer inhibitors, ${ }^{[2]}$ whereas 2-aminothiazole derivatives are inhibitors of $\operatorname{cdk} 5 / \mathrm{p} 25$ and thus, potentially useful for the treatment of Alzheimer's disease and other neurodegenerative disorders. ${ }^{[3]}$ Likewise, 5-arylidene-2-imino-4-thiazolidinones exhibit significant levels of antiinflammatory activity. ${ }^{[4]}$ Recently, Kurth and coworkers have reported the synthesis of triazolobithiazole derivatives with cystic fibrosis corrector activity. ${ }^{[5]}$ Because of the wide spectrum of activity shown by the thiazole moiety, the design of amenable synthetic approaches to new and complex thiazole derivatives is still an attractive challenge and a focus of great interest.

The Diels-Alder reaction is one of the most intensively studied organic processes, which affords six-membered products via carbon-carbon bond making. ${ }^{[6]}$ The Diels-Alder reaction continues to play a central role in the construction of a large number of molecules of biological interest. ${ }^{[7]}$ Synthetic plans that incorporate this reaction depend on our ability to effectively predict the relative reactivities of dienes and dienophiles. ${ }^{[7 a]}$ Thus, the Diels-Alder reaction is important not only from a synthetic standpoint but also from a theoretical view. ${ }^{[8]}$

An area of great interest in the Diels-Alder reaction involves the use of vinyl heterocycles as the dienic component. ${ }^{[9]}$ Diverse polycyclic structures have been synthesized in this way from vinylfurans, ${ }^{[10]}$ vinylindoles, ${ }^{[11]}$ vinylpyrroles ${ }^{[12]}$ and vinylimidazoles. ${ }^{[13]}$ The reactivity of heterocyclic dienes is determined by the nature and number of heteroatoms and, in case of heteroaromatic compounds, also by their aromatic characters. ${ }^{[14]}$ Evaluation of the reactivity of the parent compounds in the vinylheteroarene series is of general interest for predicting the outcome of Diels-Alder reactions and other pericyclic processes, especially with regard to synthesis planning.

Although it is generally assumed that thiazoles show unfavourable Diels-Alder reactions due to their considerable aromatic stabilization, ${ }^{[14-15]}$ we have reported that 4alkenylthiazoles behave as excellent dienes in [4+2] cycloadditions (Scheme 1). ${ }^{[16]}$ They show a huge preference for the extra-annular cycloaddition due to the higher reactivity of the diene system including the side-chain double bond. This way of interacting allows substituted condensed heterocyclic systems to be synthesized.

Scheme 1. [4+2] cycloadditions of 4-alkenyl- and 5-alkenylthiazoles with a generic dienophile $\mathrm{X}=\mathrm{Y}$.

Recently, we have also established that an amino group at C-2 of the thiazole ring has a powerful activating effect, ${ }^{[16 c]}$ rendering electron density to the alkenylthiazole skeleton. ${ }^{[15 a, 17]}$ The [4+2] cycloadditions of 4-alkenylthiazoles emerges as a completely new methodology for the access to new polycyclic thiazole derivatives.

As a part of our program to expand the scope of this new methodology, we decided to investigate if 5-alkenylthiazoles behave as dienes in cycloaddition reactions as efficiently as their 4alkenyl counterparts do (Scheme 1). For obvious reasons, the amino group at C-2 was preserved. Herein, we disclose our results regarding the synthesis and reactivity of 5-alkenyl-2aminothiazoles as dienes in [4+2] cycloaddition reactions, including issues related to stereocontrol and regiochemistry. The operation of a concerted versus a stepwise mechanism is also thoroughly discussed.

## Results and Discussion

## HOMO energies of 5-vinylthiazole 1a and 5-alkenyl-2aminothiazoles 1b,c

The HOMO energies of the 5-vinylthiazole 1a and 5-alkenyl-2aminothiazoles $\mathbf{1 b}, \mathbf{c}$ (Figure 1) were obtained through single-point Hartree-Fock (HF) calculations with the $6-31 \mathrm{G}$ basis set at the B3LYP/6-31G geometries, as this procedure has been shown to provide more accurate orbital energies than the B3LYP level. ${ }^{[18]}$ The computed B3LYP/6-31G structures of thiazoles 1a-c in their reactive $s$-cis conformations are shown in Figure 2. In Table 1 we summarize the HOMO energies and the $2 p_{z}$ eigenvectors of the HOMOs of dienes 1a-c. Besides, the HOMO energies and the $2 p_{z}$ eigenvectors of the HOMOs of the 4 -vinylthiazole $\mathbf{2 a}$ and 4-alkenyl-2-aminothiazoles $\mathbf{2 b}$, $\mathbf{c}$ have been also included in Table 1 for comparison.

[a] Data published in ref. [16a]. [b] Data published in ref. [16c].

The values included in Table 1 show that the change of the alkenyl substituent from carbon- 4 to carbon- 5 of the thiazole ring does not significantly affect the HOMO value. This observation is true for both, 2 -unsubstituted (compare entries 1 and 4) and 2aminothiazoles (compare entries 2 and 3 with 5 and 6 ). The data collected in Table 1 also demonstrate the same conclusion that we extracted previously: ${ }^{[16 c]}$ the HOMO energy values are enhanced by the presence of a phenyl group at $R^{1}$ (compare entries 2 and 3 and entries 5 and 6 ). Considering these results, 5 -alkenyl-2aminothiazole 1c should be the most reactive diene.

## Synthesis of 5-alkenyl-2-aminothiazoles 1d-f

On the basis of the preceding observations, 5-alkenyl-2aminothiazoles 1d-f were selected as the most appropriate dienes (Scheme 2). Our method of synthesizing thiazoles 1d-f is based on a formerly reported method ${ }^{[19]}$ for preparing related 2-amino-5acylthiazoles, and it starts from $N, N$-dimethylthiourea (3). It comprises a three-step route in which none of the intermediates are isolated (Scheme 2). The first step was the reaction of $\mathbf{3}$ with $N, N-$ dimethylformamide dimethyl acetal (DMF-DMA), which led to the iminothiourea $\mathbf{4}$ in quantitative yield. After removal of the solvent and the excess of DMF-DMA under reduced pressure, the ${ }^{1} \mathrm{H}$ NMR spectrum of the reaction mixture showed only resonances ascribable to the iminothiourea 4. Among these signals are four singlets in the range of $3.06-3.50 \mathrm{ppm}$, attributable to the resonances of the four methyl groups and one more singlet at 8.75 ppm , assigned to the iminic hydrogen atom. The iminothiourea 4 was reacted with the corresponding cinnamyl bromides $\mathbf{5}$, leading to the salts 6a-c. Further in situ treatment of 6a-c with triethylamine led to the thiazoles 1d-f (Table 2).

Scheme 2. Synthesis of 5-alkenyl-2-aminothiazoles 1d-f from $N, N-$ dimethylthiourea (3).

Table 2. Synthesis of 5-alkenyl-2-aminothiazoles 1d-f from $\mathrm{N}, \mathrm{N}$ dimethylthiourea (3).

| Entry | Ar | Compound | Yield (\%) |
| :---: | :---: | :---: | :---: |
| 1 | Ph | $\mathbf{1 d}$ | 50 |
| 2 | $4-\mathrm{O}_{2} \mathrm{NC}_{6} \mathrm{H}_{4}$ | $\mathbf{1 e}$ | 80 |
| 3 | $4-\mathrm{MeOC}_{6} \mathrm{H}_{4}$ | $\mathbf{1 f}$ | 13 |

As depicted in Table 2, higher yields were obtained when the phenyl group, labelled as Ar, contains an electron-acceptor functionality such as a nitro group (Table 2, entry 2). However, the global yield dropped to $13 \%$ if an electron-donating substituent, such as a methoxy group, is attached to the same position (Table 2, entry 3). In this latter case a great amount of unreacted iminothiourea intermediate (4) was recovered.

We assayed several modifications of this method for improving the yields, as a change in the number of equivalents of base, the use of an alternative one, i.e. DIPEA (diisopropyl ethyl amine) or an increase of the temperature of the reaction. However, the results were negative in all cases. We concluded that the high dependence of the yields of thiazoles $\mathbf{1 c - d}$ on the electronic nature of the substituents at the Ar group, is probably related with the type of intermediates involved in the mechanism of this transformation. As shown in Scheme 3, the role of the $\mathrm{Et}_{3} \mathrm{~N}$ is the abstraction of a proton adjacent to the sulfur atom in the salts $\mathbf{6}$, generating the corresponding sulfur ylides $7 \mathbf{a} \mathbf{a}$. The negative charge of 7 would be delocalized through the adjacent C-C double bond and the Ar group attached to it. The intramolecular nucleophilic addition of the ylidic carbon atom in 7 to the electrophilic C-4 should lead to the thiazolines $\mathbf{8}$. In a final step, the elimination of dimethylamine in 8 would yield thiazoles 1. Expectedly, the presence of an electron-acceptor functionality in Ar would favour not only the abstraction of the proton at C-5 by increasing their acidity through resonance effects, but also the initial nucleophilic substitution at the cinnamyl bromide for forming the sulfonium salts 6 .

Scheme 3. Mechanism of the transformation of intermediates 6a-c into 5alkenylthiazoles 1d-f.

## [4+2] cycloadditions of 5-alkenyl-2-aminothiazoles 1d-f

The HOMO values of the 5-alkenyl-2-aminothiazoles 1a-c are higher than those of their 4 -alkenylic counterparts ${ }^{[16 c]}$ and thus, we expected also higher reactivities. However, the reactions of thiazoles 1d-f with $N$-phenylmaleimide (NPM) under analogous reaction conditions, i.e. acetonitrile at room temperature, led to low conversions of the starting materials even with long reaction times. Finally, we could obtain the cycloadducts endo-9a-c under refluxing acetonitrile in excellent yields (Scheme 4, Table 3, entries 1-3). The reaction of $\mathbf{1 d}$ with maleic anhydride (MA) at room temperature gave the tetrahydrofuro[3,4-e] benzothiazole-6,8dione endo-9d in good yield (Table 3, entry 4). The X-ray crystal structure of 9a confirmed that the isolated stereoisomer is the result of an endo approach (see below).

Scheme 4. Reactions of 5-alkenyl-2-aminothiazoles 1d-f with NPM and MA (Ar, X, $T$ and $t$ defined in Table 3).

Table 3. Reactions of 5-alkenyl-2-aminothiazoles 1d-f with NPM and MA.

| Entry | Ar | X | $T\left({ }^{\circ} \mathrm{C}\right)$ | $t(\mathrm{~h})$ | Compound | Yield <br> $(\%)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | Ph | NPh | reflux | 24 | endo-9a | 97 |
| 2 | $4-\mathrm{O}_{2} \mathrm{NC}_{6} \mathrm{H}_{4}$ | NPh | reflux | 72 | endo- $9 \mathbf{b}$ | 98 |
| 3 | $4-\mathrm{MeOC}_{6} \mathrm{H}_{4}$ | NPh | reflux | 24 | endo-9c | 90 |
| 4 | Ph | O | r.t. | 24 | endo- 9 d | 90 |

We conducted a competition experiment between thiazoles 1d and $1 \mathbf{f}$ to compare their relative reactivities toward NPM (Scheme 5). Thus, three equivalents of NPM were added to a solution containing equimolecular quantities of $\mathbf{1 d}$ and $\mathbf{1 f}$. The reaction mixture was kept at room temperature and the ratio of endo-9a:endo-9c was determined at different reaction times by ${ }^{1} \mathrm{H}$ NMR spectroscopy (Table 4). Our expectation was that the more electron-rich diene $\mathbf{1 f}$ would react faster. ${ }^{[6 a]}$ However, as reflected in Table 4, the presence of a methoxy group in the aromatic group attached to the diene fragment does not affect its reactivity in a significant way.

Scheme 5. Competition experiment between 1d and 1f toward NPM. The reaction time $(t)$ is specified in Table 4.

Table 4. Competition experiment between 1d and $\mathbf{1 f}$ toward NPM.

| Entry | $t(\mathrm{~h})$ | Conv. $(\%)^{[\mathrm{a}, \mathrm{b}]}$ | endo-9a:endo-9c |
| :---: | :---: | :---: | :---: |
| 1 | 15 | 9 | $48: 52$ |
| 2 | 24 | 11 | $47: 53$ |
| 3 | 48 | 15 | $46: 54$ |

[a] Global conversion of 1d plus 1f. [b] Determined by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ analysis of characteristic signals directly on the reaction mixture (error $\pm 5 \%$ of the stated value).

Contrary to that observed for 4-alkenylthiazoles, ${ }^{[16 \mathrm{a}, 16 \mathrm{c}]}$ primary cycloadducts endo-9 were not prone to experience a further 1,3hydrogen migration, in spite of the fact that this transformation would lead to the rearomatization of the thiazole ring (Scheme 6).

Scheme 6. [4+2] cycloaddition of a generic 5-alkenyl-2aminothiazole $\mathbf{1}$ and further 1,3-hydrogen migration step to give endo-10.

In order to promote the 1,3 -hydrogen migration, the cycloadduct endo-9a was heated in acetonitrile solution at $100{ }^{\circ} \mathrm{C}$ for 24 h (Scheme 7). In this way, the fully aromatized compound $\mathbf{1 1}$ was obtained.

Scheme 7. Thermal treatment of endo-9a.

The reaction of $\mathbf{1 d}$ with 4-phenyl-1,2,4-triazoline-3,5-dione (PTAD) in toluene at room temperature led to a mixture of diastereoisomeric cis-12 and trans-12 in a 87:13 ratio (Scheme 8). In our hands, the separation of the two diastereomers by chromatographic techniques or crystallization could not be achieved due to their similar $R_{\mathrm{f}}$ values and solubilities.

Scheme 8. Reaction of 5-alkenyl-2-aminothiazole 1d with PTAD.

5-Alkenyl-2-aminothiazoles 1d-f were reacted with tetracyanoethylene (TCNE) in distilled $\mathrm{CHCl}_{3}$ to give the cis dihydrobenzothiazoles 13a-c in excellent yields (Scheme 9, Table 5). Curiously, the use of commercial $\mathrm{CHCl}_{3}$ lead to a mixture of unaltered starting materials. ${ }^{[20]}$

Scheme 9. Reaction of 5-alkenyl-2-aminothiazoles 1d-f with TCNE (Ar and $t$ specified in Table 5).

Table 5. Reaction of 5-alkenyl-2-aminothiazoles 1d-f with TCNE.

| Entry | Ar | $t(\mathrm{~h})$ | Compound | Yield (\%) |
| :---: | :---: | :---: | :---: | :---: |
| 1 | Ph | 16 | $\mathbf{1 3 a}$ | 97 |
| 2 | $4-\mathrm{O}_{2} \mathrm{NC}_{6} \mathrm{H}_{4}$ | 48 | $\mathbf{1 3 b}$ | 91 |
| 3 | $4-\mathrm{MeOC}_{6} \mathrm{H}_{4}$ | 24 | $\mathbf{1 3 c}$ | 90 |

We also conducted the reaction of $\mathbf{1 d}$ with naphthoquinone in acetonitrile under reflux to give 14 in $72 \%$ of yield (Scheme 10). The oxidation of the primary adduct under the reaction conditions should be favoured by the excess of naphthoquinone present in the reaction mixture. In addition, thiazole $\mathbf{1 d}$ reacted with dimethyl acetylenedicarboxylate (DMAD) in toluene at $80^{\circ} \mathrm{C}$ leading to the dimethyl benzothiazol-4,5-dicarboxylate 15 in low yield (Scheme 10). Although other reaction conditions were assayed, i.e. toluene or acetonitrile under reflux, we could not improve this result. Similarly to other [4+2] cycloadditions with DMAD, ${ }^{[21]}$ the completely oxidized benzothiazole $\mathbf{1 5}$ was the only reaction product.

Scheme 10. Reactions of 5-alkenyl-2-aminothiazole 1d with naphthoquinone and DMAD.

Finally, the reaction of $\mathbf{1 d}$ with dimethyl fumarate (DMFu) was conducted in acetonitrile under reflux to give a mixture of four tetrahydrobenzothiazoles, the two pairs of diastereomers 16/16' and $\mathbf{1 7 / 1 7}$ ' (Scheme 11). The two primary cycloadducts 16 and $\mathbf{1 6}{ }^{\prime}$ could be separated by chromatographic techniques and were isolated in $33 \%$ and $15 \%$ yield, respectively. The tetrahydrobenzothiazoles $\mathbf{1 7}$ and $\mathbf{1 7}$ ' were isolated in a 58:46 ratio and $20 \%$ of global yield. Evidently, 17 and $\mathbf{1 7}^{\prime}$ come from an ene reaction of $\mathbf{1 6}$ and $\mathbf{1 6}^{\prime}$ with a second molecule of dimethyl fumarate. The reaction of more $\mathbf{1 d}$ with dimethyl maleate under similar reaction conditions led to a complex mixture of unidentified products.

Scheme 11. Reaction of 5-alkenyl-2-aminothiazole 1d with dimethyl fumarate.

This study confirms that the Diels-Alder reactions of 5-alkenyl-2-aminothiazoles 1 as dienes with NPM, MA, PTAD, TCNE, naphthoquinone, DMAD or dimethyl fumarate take place with the exclusive participation of the side-chain double bond (extraannular addition). Therefore, these reactions may be qualified as site-selective.

## Regioselectivity in the [4+2] cycloadditions of 5-alkenyl-2aminothiazoles 1d-f with non symmetric dienophiles

According to FMO theory, the regiochemistry of a concerted pericylic Diels-Alder reaction is controlled by the complementarity of the frontier orbitals of diene and dienophile. Thus, the more effective overlapping takes place between the ends of both reagents with the highest coefficients. ${ }^{[6 a]}$ For 5-alkenyl-2-aminothiazoles 1a-c, the coefficients of the end atoms of the dienic fragments are very similar in absolute value (Table 1). Thus, poor regioselectivities, if any, could be expected for the [4+2] cycloadditions of 5-alkenylthiazoles 1 with dienophiles. However, the reaction of $\mathbf{1 d}$ with methyl acrylate gave only a mixture of endo-18 and exo-18. The alternative regioisomeric products were not detected in the reaction mixture (Scheme 12). The diastereoisomeric cycloadducts endo-18 and exo-18 could be separated by chromatographic techniques. The reaction of $\mathbf{1 d}$ with trans- $\beta$-nitrostyrene was tested under similar reaction conditions. However, the conversion after 6 days was extremely low. The addition of an excess of dienophile led to a very complex mixture of products.

Scheme 12. Reaction of 5-alkenyl-2-aminothiazole 1d with methyl acrylate.

## Structural and configurational assignment

The relative configuration of endo-9a was unequivocally established by single-crystal X-ray analysis (Supporting Information). The configurational assignment of compounds endo$\mathbf{9 b - d}$ was done by comparison of their ${ }^{1} \mathrm{H}$ NMR data with those of
endo-9a. The coupling constants between protons $\mathrm{H}_{5} / \mathrm{H}_{5 \mathrm{a}}$ and $\mathrm{H}_{8 \mathrm{a}} / \mathrm{H}_{8 \mathrm{~b}}$ (Scheme 4) were especially informative, ranging 5.6-6.6 Hz and $7.2-7.4 \mathrm{~Hz}$, respectively. Additionally, the ${ }^{1} \mathrm{H},{ }^{1} \mathrm{H}-\mathrm{NOESY}$ spectrum of endo-9b (Supporting Information) supported the cis relative arrangement of the above mentioned protons.

The relative configurational assignment of the two stereogenic centers $\mathrm{C}_{5}$ and $\mathrm{C}_{10 \mathrm{a}}$ in compound cis- $\mathbf{1 2}$ (Scheme 8) was done by comparison of the coupling constants between their methine protons with those reported for an analogous structure. ${ }^{[16 \mathrm{~b}, 22]}$ These protons show a mutual coupling constant in the range of 2.8 Hz , a typical value for assessing a cis relationship between $\mathrm{H}_{5}$ and $\mathrm{H}_{10 \mathrm{a}}$. Similarly, protons $\mathrm{H}_{3 \mathrm{a}}$ and $\mathrm{H}_{6}$ in compounds 13a-c coupled with constant values of around 3.3 Hz , typical for a cis arrangement (Scheme 9).

The relative stereochemistry of $\mathbf{1 6}$ and $\mathbf{1 6}$ ' was established on the basis of the values of the coupling constants between the protons of the six-membered ring, and of significant cross-peaks in their respective ${ }^{1} \mathrm{H},{ }^{1} \mathrm{H}$-NOESY spectra (Figure 3 ). We worked out with the hypothesis that cycloadducts $\mathbf{1 6}$ and $\mathbf{1 6}^{\prime}$, would possess in solution the half-chair conformation depicted in Figure 3. The most significant coupling constants for these assignments are those between protons $\mathrm{H}_{3 \mathrm{a}} / \mathrm{H}_{4}, \mathrm{H}_{4} / \mathrm{H}_{5}$ and $\mathrm{H}_{5} / \mathrm{H}_{6}$. For stereoisomer 16, the coupling constant between $\mathrm{H}_{3 \mathrm{a}} / \mathrm{H}_{4}$ is 7.0 Hz , which indicates that $\mathrm{H}_{4}$ adopts a pseudoequatorial position. Additionally, the coupling constant between $\mathrm{H}_{4} / \mathrm{H}_{5}$ is 4.8 Hz , pointing to a pseudoequatorial position also for $\mathrm{H}_{5} .{ }^{[11 \mathrm{~d}]}$ For cycloadduct 16 ', the coupling constants between $\mathrm{H}_{3 \mathrm{a}} / \mathrm{H}_{4}$ and $\mathrm{H}_{4} / \mathrm{H}_{5}$ are 10.8 and 11.9 Hz , in agreement with a relative 1,2-trans disposition. The $J$ value for $\mathrm{H}_{5} / \mathrm{H}_{6}$ is 6.8 Hz pointing to a cis arrangement of these two protons. ${ }^{[11 \mathrm{~d}]}$

The most representative contacts observed in the ${ }^{1} \mathrm{H},{ }^{1} \mathrm{H}-\mathrm{NOESY}$ spectra of 16 and 16' (Supporting Information) are also displayed in Figure 3. The ${ }^{1} \mathrm{H},{ }^{1} \mathrm{H}$-NOESY spectrum of 16 shows contacts between all protons placed at the six-membered ring, indicating their spatial proximity. The crosspeaks observed between the $\mathrm{H}_{5} / \mathrm{H}_{\text {ortho }}$ and $\mathrm{H}_{3 \mathrm{a}} / \mathrm{H}_{6}$ agree well with the assignment based on the coupling constants. In the spectrum of $\mathbf{1 6}$ ', the most relevant contacts are those shown between protons $\mathrm{H}_{\text {ortho }} / \mathrm{H}_{4}$ and $\mathrm{H}_{3 \mathrm{a}} / \mathrm{H}_{5}$, suggesting that $\mathrm{H}_{3 \mathrm{a}}$ and $\mathrm{H}_{5}$ adopt a 1,3-cis arrangement. Finally, the lack of a crosspeak between $\mathrm{H}_{4} / \mathrm{H}_{5}$ and also between $\mathrm{H}_{3 \mathrm{a}} / \mathrm{H}_{4}$ is in agreement with the consecutive 1,2-trans relationship for these three protons.

Figure 3. Significant coupling constants (red colour, dashed arrows) and NOE effects (blue colour, solid arrows) for the assignment of the relative configuration of cycloadducts 16 and $\mathbf{1 6}^{\prime}$.

For exo-18, the coupling constant between $\mathrm{H}_{3 \mathrm{a}} / \mathrm{H}_{4}$ is 10.5 Hz , indicating that they adopt a 1,2-transdiaxial arrangement (Figure 4). ${ }^{[11 \mathrm{~d}]}$ The same pair of protons are coupled with a constant value of 6.6 Hz in endo-18, which agree well with their 1,2-cis relationship. ${ }^{[11 \mathrm{~d}]}$ The key NOESY crosspeak to assign the endo/exo structure of cycloadducts $\mathbf{1 8}$ is that relating $\mathrm{H}_{3 \mathrm{a}}$ and $\mathrm{H}_{4}$. Thus, whereas the spectrum of endo- $\mathbf{1 8}$ shows this contact, the spectrum of exo-18 lacks it. Additionally, the NOESY spectrum of exo-18 shows a crosspeak between $\mathrm{H}_{\text {ortho }} / \mathrm{H}_{4}$ indicating that the aromatic substituent and $\mathrm{H}_{4}$ are placed in a relative 1,3-cis position. An analogous contact was not found in the spectrum of endo-18.

Figure 4. Significant coupling constants (red colour, dashed arrows) and NOE effects (blue colour, solid arrows) for the assignment of the relative configuration of cycloadducts endo-18 and exo-18.

## Proposed mechanism for the [4+2] cycloadditions of 5-alkenyl-2-aminothiazoles 1 with dienophiles

It is commonly accepted that in most of the Diels-Alder reactions the two new $\sigma$-bonds are formed in a concerted, although not necessarily synchronous, manner. Consistent with this mode of addition, Diels-Alder reactions are generally stereospecific. ${ }^{[6 a,}{ }^{23]}$ The reactions of 5-alkenylthiazoles 1d-f with NPM, MA, TCNE or DMFu are stereospecific, being in the two former cases highly endo-selective. In principle, a concerted mechanism with an asynchronous transition state, due to the non symmetric nature of the reagents, would agree with the observed results. ${ }^{[8 b, 24]}$ However, there are two relevant experimental observations clashing with the explanation of a concerted mechanism. First, the reaction of thiazole $1 \mathbf{d}$ with PTAD lacks of stereospecificity (Scheme 8). The isolation of trans-12 excludes thus, a pericyclic concerted mechanism at least for the reaction of thiazole $\mathbf{1 d}$ with this highly reactive dienophile. More relevant is the fact that the coefficients at the end atoms of the dienic fragments in 1a-c are very similar in absolute values (Table 1). Thus, poor regioselectivities if any would be expected on this basis, contrary to the observed results. That the adequate substitution on both diene and dienophile can favour the stabilization of charges of opposite signs and tune up the mechanism of the $[4+2]$ cycloaddition from a concerted to a stepwise one is supported by previous works. ${ }^{[8 b,}{ }^{23-25]}$ Thus, we propose that cycloadditions of thiazoles $\mathbf{1 d - f}$ with dienophiles are
probably close to the concerted/stepwise boundary, being the nature of the dienophile determinant to tip the scale in favour of one or another.

We propose the following stepwise mechanism to explain the reactions of thiazole 1d with selected dienophiles such as PTAD or methyl acrylate, in which $\mathrm{X}=\mathrm{Y}$ represents a generic asymmetric dienophile (Scheme 13). First, the nucleophilic addition of the alkenylic fragment, via its $\beta$-position, of thiazoles 1 to the most electron-deficient position of the dienophile (labelled as " $X$ ") may give the zwitterionic intermediate 19. This process would be assisted by the lone pair of the amino group at $\mathrm{C}-2$, which is partially delocalized into the heterocyclic ring and the exocyclic C C double bond. The intramolecular cyclization of $\mathbf{1 9}$ by addition of the carbanionic "Y"-end to C-4 would then lead to the formal [4+2] cycloadduct 20.

Scheme 13. Stepwise mechanism for the reactions of 5-alkenyl-2aminothiazoles $\mathbf{1 d}-\mathbf{f}$ with dienophiles.

Assuming the stepwise mechanism depicted in Scheme 13, the zwitterionic intermediate resulting from the reaction of $\mathbf{1 d}$ with PTAD would be enough long-lived due to the fact that the negative charge would be placed at the electronegative nitrogen atom. This fact would favour the rotation about the C1'-C2' bond before the intramolecular cyclization takes place, which finally would lead to the formation of small quantities of trans-12. The proposed stepwise mechanism depicted in Scheme 13 agrees not only with the observed high levels of regioselectivity but also with the structure of the isolated regioisomers. Thus, the formation of cycloadducts endo-18 and exo-18 would be the result of the nucleophilic addition of the alkenylic fragment of the thiazole $\mathbf{1 d}$, via its $\beta$-position, to the most electron-deficient position of the dienophile, i.e. the $\beta$-position of the C-C double bond of methyl acrylate. Therefore, the regioselectivity of the stepwise cycloadditions of 5-alkenyl-2-aminothiazoles with non symmetric dienophiles is apparently controlled by the resonance effect of the amino group at $\mathrm{C}-2$ of the thiazole ring.

As it was pointed out previously, primary cycloadducts $\mathbf{2 0}$ are not prone to experience a further 1,3-hydrogen migration in spite of the fact that this transformation would induce the rearomatization of the thiazole ring (Schemes 6 and 7). This behaviour contrasts with that of cycloadducts resulting from a [4+2] cycloaddition of 4-alkenyl-2-aminothiazoles in which the 1,3-hydrogen migration takes place under very mild conditions. This transformation has been depicted in Scheme 14 taking 21 as a model. ${ }^{[16 c]}$ A plausible explanation for the unusual stability of cycloadducts $\mathbf{2 0}$ based on the different electronic properties of the sulfur and nitrogen atoms is given below.

Scheme 14. [4+2] cycloaddition of 4-alkenylthiazole 21 with NPM to give the primary adduct endo-22, which spontaneously experiences a further a 1,3-hydrogen migration. ${ }^{[16 \mathrm{c}]}$

The 1,3-hydrogen migration experienced by endo-22 may be intermolecular since a concerted one is expected to have a very high activation barrier. ${ }^{[26]}$ In a previous work ${ }^{[16 c]}$ we proposed that this hydrogen atom migrates with a positive charge density, being the negative charge generated at the carbon atom to which the proton was initially bonded, stabilized by the adjacent sulphur atom. ${ }^{[27]}$ Additionally, the lone pair of the exocyclic nitrogen atom in endo- 22 would be delocalized over the unsaturated fragment of the intermediate bicyclic structure, increasing the basic character of $\mathrm{C}-5$ and thus, facilitating the migration of the hydrogen atom as a proton (see the polar canonical form of endo-22 in Scheme 14). In contrast, the negative density that would be generated as a consequence of the migration of a proton in the primary cycloadducts 20 would be placed adjacent to a nitrogen atom. This situation is much less favoured compared to that previously explained for endo-22. In fact, 5-methylenethiazolines are highly stable compounds and they only isomerize to the corresponding 5methylthiazoles under acid or basic catalysis. ${ }^{[28]}$ On the contrary, as far as we know, there are no examples in the literature describing the isolation of 4-methylenethiazolines. This fact is probably a consequence of 4-methylenethiazolines being prone to tautomerize to the corresponding 4-methylthiazoles.

## Conclusions

5-Alkenyl-2-aminothiazoles 1d-f have been synthesized in excellent yields and they behave as effective dienes in [4+2] cycloadditions. The reactions of $\mathbf{1}$ with classical electron-poor dienophiles are site-selective since only the diene moiety including the formal C-C and the side-chain double bonds is implicated (extra-annular addition). The reactions with cyclic dienophiles such as NPM or MA are endo-selective. The completely oxidized cycloadduct is obtained in the reactions of 5 -alkenylthiazole 1d with naphthoquinone or DMAD. The reaction of thiazole 1d with PTAD is not stereospecific. However, the reaction of the same thiazole with methyl acrylate is highly regioselective. The collected data suggest a mechanism placed at the boundary between a concerted but highly asynchronous mechanism and a stepwise one. Presumably, the resonance effect of the amino group at C-2 of the thiazole ring is a key-controlling element for both, the reactivity and the regioselectivity observed in this type of cycloadditions.

The reactions of 5-alkenyl-2-aminothiazoles $\mathbf{1}$ with dienophiles described herein, complement those of their 4-alkenyl counterparts
previously reported. Together they open up novel routes to a great variety of complex polycyclic thiazole derivatives.

## Experimental Section

General. Melting points are not corrected. IR spectra were recorded as nujol emulsions. ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra were recorded at 300 or $401 \mathrm{MHz} .{ }^{13} \mathrm{C}$ NMR spectra were measured at 50 or 75 MHz . Mass spectra were recorded on the $\mathrm{EI}(70 \mathrm{eV})$ or $\mathrm{FAB}^{+}$mode (3-nitrobenzyl alcohol as matrix).
X-Ray structure. CCDC-945001 contains the supplementary crystallographic data for this paper. These data can be obtained free of charge form The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.
Cinnamyl bromides. Cinnamyl bromide is commercial. The 4nitrocinnamyl ${ }^{[29]}$ and 4-methoxycinnamy ${ }^{[30]}$ bromides were prepared following previously described methodologies.
Synthesis of the 5-alkenyl-2-aminothiazoles 1d-f. DMF-DMA (1.79 g; $15.0 \mathrm{mmol})$ was added to a solution of $N, N$-dimethylthiourea ${ }^{[15 \mathrm{cc}]}(1.04 \mathrm{~g}$; 10.0 mmol ) in ethanol ( 50 ml ). The reaction mixture was stirred under reflux for 4 h . The solvent and the excess of DMF-DMA were removed under reduced pressure and the resulting residue was redissolved in acetonitrile ( 50 ml ) to which the corresponding cinnamyl bromide ( 15.0 mmol ) was added. The reaction mixture was kept under reflux for 6 h and after that, triethylamine $(10 \mathrm{ml})$ was added and stirred at the same temperature for 30 min more. The solvent was evaporated until dryness. After addition of $\mathrm{H}_{2} \mathrm{O}(30 \mathrm{ml})$, the reaction mixture was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 30 \mathrm{ml})$. The organic extracts were dried under anhydrous $\mathrm{MgSO}_{4}$, the solvent removed under reduced pressure and the residue purified by silica-gel column chromatography.

[20] At longer reaction times resonances attributable to an ethoxy group started to appear. This fact may be rationalized considering the reaction of the TCNE with the traces of ethanol, used as stabilizer, contained in the commercial $\mathrm{CHCl}_{3}$. Consequently, the progressive disappearance of the reactive, i.e. TCNE, would shift the equilibrium to the starting materials.

## ((Key Topic))

5-Alkenyl-2-aminothiazoles behave as Additionally, the reactions with non active in-out dienes in [4+2] symmetric dienophiles are regioselective. cycloadditions with a wide range of dienophiles. These processes are endoselective with certain dienophiles of cyclic nature. The results point to a mechanism placed at the boundary between a highly asynchronous concerted mechanism and a stepwise one.
