[^0]The ortho-metalated complex $(S, S)-\left[\mathrm{Pd}_{2}\left\{\kappa^{2}-C, N-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \mathrm{NH}_{2}-2\right\}_{2}(\mu-\mathrm{Br})_{2}\right]$ (1b) can be prepared by refluxing in acetonitrile equimolecular amounts of $\mathrm{Pd}(\mathrm{OAc})_{2}$ and L phenylalanine methyl ester hydrochloride, followed by addition of excess of NaBr . Complex 1b reacts with 4-picoline to give the mononuclear derivative $(S)-\left[\operatorname{Pd}\left\{\kappa^{2}-C, N-\right.\right.$ $\left.\left.\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{2} \mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \mathrm{NH}_{2}-2\right\}_{2} \mathrm{Br}\left(\mathrm{NC}_{5} \mathrm{H}_{4} \mathrm{Me}-4\right)\right]$ (2), which crystal structure has been determined by X-ray diffraction. The precursor of $\mathbf{1 b}, \quad(S, S)-\left[\operatorname{Pd}_{2}\left\{\kappa^{2}-C, N-\right.\right.$ $\left.\left.\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \mathrm{NH}_{2}-2\right\}_{2}(\mu-\mathrm{Cl})_{2}\right](1 a)$ could not be isolated in a pure form, but it can be used as starting material for the synthesis of functionalized derivatives of the phenylalanine methyl ester. Thus, CO and $\mathrm{RNC}\left(\mathrm{R}=\mathrm{Xy},{ }^{t} \mathrm{Bu}\right)$ insert into the $\mathrm{Pd}-\mathrm{C}$ bond of $\mathbf{1 a}$, to afford, after depalladation, ( $S$ )-methyl 1-oxo-1,2,3,4-tetrahydroisoquinoline-3-carboxylate (3) and (S)methyl 1-R-iminium-1,2,3,4-tetrahydroisoquinoline-3-carboxylate triflate $\left(\mathrm{R}={ }^{\mathrm{t}} \mathrm{Bu}(4), \mathrm{Xy}\right.$ (5)), respectively. Reaction of complex $\mathbf{1 b}$ with bromine or iodine affords trans-( $S, S$ )$\left[\mathrm{PdBr}_{2}\left\{\mathrm{NH}_{2} \mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{X}-2\right\}_{2}\right](\mathrm{X}=\mathrm{Br}(\mathbf{6}), \mathrm{I}(7))$, which further reacts with 1,10phenanthroline (phen) to give $\left[\mathrm{PdBr}_{2}(\right.$ phen $\left.)\right]$ and $(S)-2-\mathrm{X}$-phenylalanine methyl ester $(\mathrm{X}=\mathrm{Br}$ (8), I (9)).

## Introduction

ortho-Palladation of (S)-phenylalanine (L-phenylalanine) raises an interesting problem. If the free amino acid is used, $\mathrm{N}, \mathrm{O}$-chelates involving the deprotonated carboxyl group may be formed, ${ }^{1}$ as it has been described for other amino acids. ${ }^{2}$ For instance, 4-iodo-L-phenylalanine reacts with $\left[\mathrm{PdCl}_{2}\left(\mathrm{PEt}_{3}\right)\right]_{2}$ to give the $\mathrm{N}, \mathrm{O}$-chelate complex $(\mathrm{S})-\left[\mathrm{Pd}\left\{\kappa^{2}-N, O-\right.\right.$ $\left.\left.\mathrm{NH}_{2} \mathrm{CH}\left(\mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{I}-4\right) \mathrm{CO}_{2}\right\} \mathrm{Cl}\left(\mathrm{PEt}_{3}\right)\right]^{3}$ The carboxylate groups of amino acids can be prevented from coordinating to the metal by using ester derivatives. ${ }^{4,5}$ Even though, a second problem remains: ortho-metalation of primary amines has been reported to be difficult, especially if the metallacycle to be formed is a six-membered ring. ${ }^{6}$ This second issue has been avoided by using functionalized ${ }^{7}$ or N -substituted ${ }^{4,8}$ amino groups. However, orthometalation of primary amines is difficult, but it can be carried out if appropriate experimental conditions are used. ${ }^{9-14}$
ortho-Palladated ( $S$ )-phenylalanine complexes are interesting for at least three reasons. First of all, palladium complexes containing amino acids as ligands ${ }^{15-17}$ as well as cyclopalladated complexes ${ }^{17,18}$ have attracted great interest because their potential cytotoxic activity. Secondly, they can be useful precursors to prepare functionalized derivatives of Lphenylalanine, since complexes containing cyclopalladated amines have found widespread application in organic synthesis. ${ }^{19-21}$ Among the possible derivatives, the ortho-halogenated amino acids are particularly interesting, as they are not easily prepared by other methods, such as direct electrophilic substitution, and, in addition, they can be used for preparing other amino acids through palladium-catalyzed reactions. Barluenga et al. have recently reported a regioselective method to prepare ortho-iodinated phenylalanine-containig peptide sequences, ${ }^{22}$ but the method cannot be applied to the methyl ester of the amino acid. ${ }^{23}$ Finally, optically active palladacycles are suitable auxiliary reagents for the resolution of racemic
mixtures and determination of enantiomeric purity and absolute configuration of chiral phosphines, ${ }^{12,24}$ amino acids, ${ }^{25}$ and other ligands. ${ }^{26}$

Fuchita et al. reported the cyclopalladation of ( $R$ )-2-phenylglycine methyl ester, an amino acid derivative with an unprotected amino group which gives a five-membered palladacycle, by reacting palladium acetate with the hydrochloride salt of the amino acid ester in acetone. ${ }^{27}$ Nevertheless, the same reaction conditions were reported to fail when trying to prepare the analogous compound containing ( $S$ )-phenylalanine methyl ester, our target complex in this article.

Insertion of CO into the $\mathrm{Pd}-\mathrm{C}$ bond of ortho-palladated tertiary amines has been widely investigated, ${ }^{8,19,28-30}$ whereas the same reaction with primary benzylamines has been only superficially examined. Thus, a preliminary communication by Parkins et al. in 1984 described the reaction of $\left[\mathrm{Pd}\left(\kappa^{2}-C, N-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{2} \mathrm{NH}_{2}-2\right) \mathrm{I}\right]_{2}$ with CO in methanol at room temperature to give phthalimidine and palladium metal, although experimental procedures and the yield were not stated. ${ }^{31}$ Dyke et al. in 1986 observed a similar reaction using chloroform or benzene as solvent, although the expected phthalimidine was not obtained pure. ${ }^{32}$ We report here that (S)-1-oxo-3-methoxycarbonyl-1,2,3,4-tetrahydroisoquinoline can be obtained by carbonylation of ortho-palladated ( $S$ )-phenylalanine methyl ester. This is a particularly interesting compound ${ }^{33}$ as it has been extensively used to study the steric course and stereospecificity of $\alpha$-chymotrypsin-catalyzed reactions. ${ }^{34,35}$ It has also been used as antiallergic agent, to prevent the physical manifestation of atopic allergic reactions. ${ }^{36}$ Recently, a convenient large-scale synthesis of the $R$ enantiomer has been reported, using the amino acid methyl ester and triphosgene as starting materials. ${ }^{37}$

The reaction of five-membered cyclopalladated benzylamines and isocyanides allows the isolation of the corresponding isoindolinium salts. ${ }^{31,38}$ Here we report that the six-
membered cyclopalladated ( $S$ )-phenylalanine methyl ester allows the synthesis of tetrahydro isoquinolines.

## Results and Discussion

Synthesis and Structure of ortho-Metalated Complexes. When (S)$\mathrm{PhCH}_{2} \mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \mathrm{NH}_{2} \cdot \mathrm{HCl}$ (L-phenylalanine hydrochloride) is reacted with $\mathrm{Pd}(\mathrm{OAc})_{2}$ in 1:1 molar ratio in acetonitrile for 6 days, an orange solid $\mathbf{A}$ is isolated, which ${ }^{1} \mathrm{H}$ NMR shows very broad signals that cannot be easily assigned. Nevertheless, in the aromatic region of the spectrum, there are signals corresponding to the ortho-metalated and the non-ortho-metalated aryl ring of the starting amino acid derivative. There are also two signals in the region corresponding to the OMe groups, which relative integrals indicate an average molar ratio $1: 0.3$. On the other hand, no acetate signals are present. The components of the mixture cannot be separated by fractional crystallization or by chromatography, although its reactivity shows that the ortho-metalated complex $(S, S)-\left[\mathrm{Pd}_{2}\left\{\kappa^{2}-C, N-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{2} \mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Me}^{2}\right) \mathrm{NH}_{2}-2\right\}_{2}(\mu-\right.$ $\mathrm{Cl}_{2}$ ] (1a) is the main component (Scheme 1). Thus, this mixture A can be used as starting material to synthesize in good yields some derivatives of $\mathbf{1 a}$.

Other reaction conditions (solvent, temperature, time) were tested to prepare 1a: i) acetonitrile at $80^{\circ} \mathrm{C}$ for $4-8 \mathrm{~h}$; ii) toluene at 60 or $75^{\circ} \mathrm{C}$ for 12 h ; iii) acetic acid at $60^{\circ} \mathrm{C}$ for 24 h . In all cases, decomposition to $\operatorname{Pd}(0)$ took place and the mixture obtained was not as rich in $\mathbf{1 a}$ (tested by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ ) as in $\mathbf{A}$. However, we succeeded in isolating the pure bromobridged dinuclear ortho-metalated complex $(S, S)-\left[\mathrm{Pd}_{2}\left\{\kappa^{2}-C, N-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{2} \mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \mathrm{NH}_{2}{ }^{-}\right.\right.$ $\left.2\}_{2}(\mu-\mathrm{Br})_{2}\right]$ (1b), by reacting the mixture $\mathbf{A}$ with NaBr and recrystallizating the crude product. 4-Picoline (pic) splits the bromide bridges in complex 1b to give the mononuclear complex (S)-[Pd\{ $\left.\kappa^{2}-C, N-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{2} \mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \mathrm{NH}_{2}-2\right\}_{2} \mathrm{Br}($ pic $\left.)\right]$ (2). Of the two possible isomers for
complex 2, only the one with the two nitrogen atoms in mutually trans position is obtained, as proved by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ NMR and X-ray diffraction studies. This is the normal behavior for benzylamine palladacycles, ${ }^{21,39}$ although a notable exception has recently been reported. ${ }^{40}$

## Scheme 1

The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of complexes $\mathbf{1 b}$ and 2 are in agreement with the proposed structures. The ${ }^{1} \mathrm{H}$ NMR spectrum of complex $\mathbf{1 b}$ shows a set of three different signals, corresponding to the four remaining protons in the ortho-metalated ring: H3 (see numbering scheme in experimental section) appears as a doublet at $7.38 \mathrm{ppm}, \mathrm{H} 5$ as a triplet at 6.88 ppm , and H 4 and H 6 as a multiplet between $6.76-6.91 \mathrm{ppm}$. A similar pattern is observed in the ${ }^{1} \mathrm{H}$ NMR spectrum of the mononuclear complex 2 although, in this case, H 3 is significantly shifted to lower frequencies ( $\Delta \delta=-0.92 \mathrm{ppm}$ ) due to the anisotropic shielding from the picoline ring. ${ }^{41}$ In the ${ }^{13} \mathrm{C}$ NMR spectra of complexes $\mathbf{1 b}$ and $\mathbf{2}$, the resonances due to the carbon atoms bonded to $\mathrm{Pd}(140.8 \mathrm{ppm}, \mathbf{1 b} ; 147.4 \mathrm{ppm}, \mathbf{2})$ are deshielded with respect to that of the corresponding free ligand ( 129.3 ppm in DMSO-d ${ }^{6}$ ), as observed in other cyclopalladated complexes. ${ }^{13,14,42}$

The crystal structure of complex 2 (Figure 1) shows the palladium atom in a distorted square-planar environment (mean deviation of the plane $0.09 \AA$ ) with a dihedral angle of $8.3^{\circ}$
between the $\mathrm{N}(1)-\mathrm{Pd}(1)-\mathrm{C}(1)$ and $\mathrm{N}(2)-\mathrm{Pd}(1)-\mathrm{Br}(1)$ planes. The chelated amino acid ligand forms a six-membered metalacycle with a boat conformation. These features are similar to those of analogous complexes containing other phenethylamine derivatives. ${ }^{11,13}$ The nitrogen atom of the amine and the nitrogen atom of 4-picoline are mutually trans and the pyridine ring is rotated $65.3^{\circ}$ with respect to the phenyl ring to avoid steric hindrance.

Figure 1. Thermal ellipsoid plot ( $50 \%$ probability) of 2 along with the labeling scheme. Selected bond lengths $(\AA)$ and angles $\left(^{\circ}\right): \operatorname{Pd}(1)-\operatorname{Br}(1) 2.5458(6), \operatorname{Pd}(1)-\mathrm{N}(1) 2.066(4)$, $\operatorname{Pd}(1)-\mathrm{C}(1) 1.999(5), \operatorname{Pd}(1)-\mathrm{N}(2) 2.054(4), \operatorname{Br}(1)-\mathrm{Pd}(1)-\mathrm{N}(1) 85.39(12), \mathrm{N}(1)-\mathrm{Pd}(1)-\mathrm{C}(1)$ 92.19(18), $\mathrm{C}(1)-\mathrm{Pd}(1)-\mathrm{N}(2) 90.22(17), \mathrm{N}(2)-\mathrm{Pd}(1)-\mathrm{Br}(1) 92.81(11)$.

Each molecule of complex $\mathbf{2}$ is connected to other four molecules through hydrogen bonds, giving a tridimensional network. Along the $b$ axis, two adjacent molecules (A and C; Figure 2) are associated through a double interaction between the bromine atom of one molecule (C) and one hydrogen of the methyl group of the other (A) (Br1C $\cdots \mathrm{H} 10 \mathrm{~A}-\mathrm{C} 10 \mathrm{~A})$ and one hydrogen of the amino group of the later molecule (A) and the oxygen atom of the carbonyl group of the former (A) (N1C-H01C $\cdots \mathrm{O} 2 \mathrm{~A})$. Besides, the same bromine atom is
associated with two aromatic picoline hydrogens, belonging each of them to other two different molecules (Figure 3).

Figure 2. View of the hydrogen bond interactions along the $b$ axis in complex 2. Only Pd and atoms involved in the H bonding are labeled. Details (including symmetry operators) are given in the Supporting Information.

Figure 3. View of the hydrogen bond interaction between aromatic hydrogen and bromine atoms in complex 2. Only Pd and atoms involved in the H bonding are labeled. Details (including symmetry operators) are given in the Supporting Information.

## Reaction with Carbon Monoxide. Synthesis of (S)-1-oxo-3-methoxycarbonyl-

 1,2,3,4-tetrahydroisoquinoline (3). As stated in the Introduction, two previous works described the reaction of $\left[\mathrm{Pd}\left(\kappa^{2}-C, N-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{2} \mathrm{NH}_{2}-2\right) \mathrm{I}_{2}\right.$ with CO to give phthalimidine and palladium metal, although the experimental procedures and the yield were not stated in the first one ${ }^{31}$ and the phthalimidine was not obtained pure in the other. ${ }^{32}$ The reaction of the mixture $\mathbf{A}$ with CO in $\mathrm{CHCl}_{3}$ at room temperature have allowed us to prepare $(S)$-1-oxo-3-methoxycarbonyl-1,2,3,4-tetrahydroisoquinoline (3) (Scheme 2). The good isolated yield ( $64 \%$ from phenylalanine methyl ester hydrochloride) proves that $\mathbf{A}$ is mainly the orthometalated complex 1a.The reaction conditions used to prepared the tetrahydroisoquinoline derivative $\mathbf{3}$ are milder than those used in analogous reactions to prepare 2-methyl-phthalimidine from orthopalladated $\mathrm{N}, \mathrm{N}$-dimethylbenzylamine (xylene, $100{ }^{\circ} \mathrm{C}$ and 1 atm of CO-pressure ${ }^{28}$ or $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, room temperature and 2 atm of CO-pressure ${ }^{29}$ ) but similar to those used to prepare 2-methyl-3-carboxymethyl-phthalimidine from ortho-palladated N,N-dimethylphenylglycine, ${ }^{8}$ although in the later, a nitrogen atmosphere was used. As mentioned in the Introduction, $\mathbf{3}$ has been used to study the steric course and stereospecificity of $\alpha$-chymotrypsin-catalyzed reactions, ${ }^{34,35}$ and as antiallergic agent, to prevent the physical manifestation of atopic allergic reactions. ${ }^{36}$ Compound 3 has been synthesized mostly by cyclation of N -acyl $\beta$ arylethylamines, through procedures that involve some drastic reaction conditions or moisture sensitive catalysts. ${ }^{34,43}$ Recently, a convenient large-scale synthesis of the $R$ enantiomer has been reported, using the amino acid methyl ester and triphosgene as starting materials. ${ }^{37}$

Scheme 2. Synthesis of (S)-1-oxo-3-methoxycarbonyl-1,2,3,4-tetrahydroisoquinoline (3).

Orito et al. have reported a $\operatorname{Pd}(\mathrm{II})$-catalyzed carbonylation of N -alkyl- $\omega$ arylalkylamines to afford five or six-membered benzolactams. ${ }^{44}$ In these conditions, carbonylation of primary amines does not produce benzolactams but ureas. The key step in these reactions seems to be the metalation of the amine. This result is not surprising since ortho-metalation of primary amines does not occur in the used reaction conditions when an excess of amine is present. ${ }^{45}$ Our method, although not catalytic, allows the synthesis of a benzolactam from a primary amine and CO.

## Reactions with Isocyanides. Synthesis and Structure of [(S)-methyl 1-R-iminium-

 1,2,3,4-tetrahydroisoquinoline-3-carboxylate] triflate $\left[\mathrm{R}={ }^{\mathrm{t}} \mathrm{Bu}\right.$ (4), 2,6-Me2 $\mathrm{C}_{6} \mathrm{H}_{3}$ (Xy) (5)]. It has been reported that reaction of cyclopalladated benzylamines and isocyanides in refluxing toluene allows the isolation of the corresponding isoindolinium salts. ${ }^{31,38}$ The present availability of cyclopalladated phenethyl amines prompted us to extend this work to the synthesis of six-membered N -heterocycles. Thus, the mixture $\mathbf{A}$ was treated with isocyanide ( $\mathrm{RNC}, \mathrm{R}={ }^{\mathrm{t}} \mathrm{Bu}, \mathrm{Xy}$ ) and thallium(I) triflate (1:2:2). After removing TlCl , the resulting solution was refluxed in toluene for 7 hours, upon which time formation of $\operatorname{Pd}(0)$ was observed. From the mother liquors, the tetrahydro isoquinoline derivatives $\mathbf{4}$ and $\mathbf{5}$ could be isolated (Scheme 3).

## Scheme 3

According to previous studies, ${ }^{8,38,46}$ it is reasonable to assume that the first step in the formation of the tetrahydro isoquinoline derivative is the coordination of the isocyanide to the ortho-metalated fragment to give the adduct $\mathbf{B}$, followed by insertion into the $\mathrm{Pd}-\mathrm{C}$ bond to give an iminoacyl complex $\mathbf{C}$. There are some examples of such dimeric bridging iminoacyl palladium complexes. ${ }^{29,47}$ The instability of this triflato derivative and the strain of the sevenmembered ring can explain its decomposition and the formation of palladium(0) and the salt $\mathbf{4}$ or 5 .

Scheme 4. Proposed reaction pathway for the synthesis of 4 and 5.

These reactions can be performed without thallium triflate, but yields are lower. Besides, a mixture of the chloride salts and the free bases are obtained (tested by ${ }^{1} \mathrm{H}$ NMR).

Recently, Saluste et al. have reported the palladium catalyzed synthesis of cyclic amidines, starting from 2-bromobenzylamine or 2-bromophenethylamine, ${ }^{\mathrm{t}} \mathrm{BuNC}$ and $\mathrm{CsCO}_{3} .{ }^{48}$ Nevertheless, it is necessary to point out the restricted availability of 2-halobenzylamines and the limitations of the process, that seems to give only good yields for tertalkylisonitriles.

The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of compounds $\mathbf{4}$ and $\mathbf{5}$ are in agreement with the proposed structures. Additionally, the crystal structure of both compounds have been determined by X-ray diffraction. The similar $\mathrm{N}-\mathrm{C}$ bond distances in the groups $\mathrm{N}(2)-\mathrm{C}(9)$ -$\mathrm{N}(1)[\mathrm{N}(2)-\mathrm{C}(9) 1.3215(18), \mathrm{C}(9)-\mathrm{N}(1) 1.3248(18) \AA]$ (4) and $\mathrm{N}(1)-\mathrm{C}(17)-\mathrm{N}(2)[\mathrm{N}(1)-$ $\mathrm{C}(17) 1.318(3), \mathrm{C}(17)-\mathrm{N}(2) 1.312(3) \AA](5)$ and the significantly longer distances of $\mathrm{N}(1)$ and $\mathrm{N}(2)$ with their other neighbors $[\mathrm{N}(2)-\mathrm{C}(10) 1.4990(17), \mathrm{N}(1)-\mathrm{C}(8), 1.4625(16) \AA(4) ; \mathrm{N}(1)-$ $\mathrm{C}(1) 1.443(3), \mathrm{N}(2)-\mathrm{C}(18), 1.457(3) \AA(5)]$ suggest that a delocalization of electron density occurs between the atoms $\mathrm{N}(2), \mathrm{C}(9)$ and $\mathrm{N}(1)$ in $\mathbf{4}$, and $\mathrm{N}(1), \mathrm{C}(17)$ and $\mathrm{N}(2)$ in 5 . Additionally, the angles $\mathrm{C}(9)-\mathrm{N}(2)-\mathrm{C}(10) \quad\left[129.35(12)^{\circ}\right]$ in 4 and $\mathrm{C}(17)-\mathrm{N}(1)-\mathrm{C}(1)$ [124.45(19) ${ }^{\circ}$ ] in 5 are far away from the $\mathrm{sp}^{3}$ hybridization for $\mathrm{N}(2)$ and $\mathrm{N}(1)$, respectively, if a lone pair were assumed on these atoms. The atoms $\mathrm{C}(8), \mathrm{N}(1), \mathrm{C}(9), \mathrm{C}(2), \mathrm{N}(2)$ and $\mathrm{C}(10)$ in 4 and $C(18), N(2), C(17), C(11), N(1)$ and $C(1)$ in 5 are coplanar (mean deviation from the plane 0.0459 and $0.0417 \AA$, respectively).

In both compounds, the cationic units are connected to the triflate groups through hydrogen bonds (nine interactions with three different triflates for compound 4, and six interactions with three different triflates for compound 5). In the cation of compound 5, there is also a hydrogen bond between the oxygen atom of the $\mathrm{C}=\mathrm{O}$ group and one aromatic
hydrogen of the phenyl ring (O1A $\cdots \mathrm{H} 15 \mathrm{D}-\mathrm{C} 15 \mathrm{D})$. This interaction leads to zig-zag chains along the $b$ axis (see Figure 6).

Figure 4. Thermal ellipsoid plot (50\% probability) of the cation of 4 along with the labeling scheme. Selected bond lengths $(\AA)$ and angles $\left({ }^{\circ}\right): N(2)-C(10) 1.4990(17), N(2)-C(9)$ $1.3215(18), \mathrm{N}(1)-\mathrm{C}(9) 1.3248(18), \mathrm{N}(1)-\mathrm{C}(8) 1.4625(16), \mathrm{C}(2)-\mathrm{C}(9) 1.4809(18), \mathrm{C}(9)-$ $\mathrm{N}(2)-\mathrm{C}(10) \quad 129.35(12), \mathrm{C}(9)-\mathrm{N}(1)-\mathrm{C}(8)$ 122.87(12), $\mathrm{N}(1)-\mathrm{C}(9)-\mathrm{N}(2)$ 121.78(13), $\mathrm{N}(1)-$ $\mathrm{C}(9)-\mathrm{C}(2) 118.46(12), \mathrm{N}(2)-\mathrm{C}(9)-\mathrm{C}(2) 119.75(12)$.

Figure 5. Thermal ellipsoid plot (50\% probability) of the cation of $\mathbf{5}$ along with the labeling scheme. Selected bond lengths $(\AA)$ and angles $\left({ }^{\circ}\right): N(1)-C(1) 1.443(3), N(1)-C(17) 1.318(3)$, $\mathrm{N}(2)-\mathrm{C}(17) \quad 1.312(3), \mathrm{N}(2)-\mathrm{C}(18)$ 1.457(3), $\mathrm{C}(17)-\mathrm{C}(18)$ 1.479(3), $\mathrm{C}(1)-\mathrm{N}(1)-\mathrm{C}(17)$ 124.45(19), $\mathrm{C}(17)-\mathrm{N}(2)-\mathrm{C}(18) 122.54(19), \mathrm{N}(2)-\mathrm{C}(17)-\mathrm{N}(1) 120.8(2), \mathrm{N}(2)-\mathrm{C}(17)-\mathrm{C}(11)$ 119.22(19), $\mathrm{N}(1)-\mathrm{C}(17)-\mathrm{C}(11) 120.00(19)$.

Figure 3. View of the hydrogen bond interaction between aromatic hydrogen and oxygen atoms of $\mathrm{C}=\mathrm{O}$ group in compound 5 . Only atoms involved in the H bonding are labeled. Details (including symmetry operators) are given in the Supporting Information.

Synthesis and Structure of 2-Halo Derivatives. Stoichiometric aromatic halogenation of tertiary amines through cyclopalladated complexes is a known process. ${ }^{19,49,50}$ However, the extension to the corresponding primary amines has only very recently reported by us. ${ }^{14}$ The reaction of complex $\mathbf{1 b}$ with $\mathrm{Br}_{2}$ or $\mathrm{I}_{2}$, in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature, afforded trans- $\left[\mathrm{PdBr}_{2}\left\{\mathrm{NH}_{2} \mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \mathrm{Me}_{2} \mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{X}-2\right\}_{2}\right](\mathrm{X}=\mathrm{Br}, 6 ; \mathrm{I}, 7)$ in good yields (Scheme 3). We have proposed that the initial step of the reaction is the oxidative addition of iodine or bromine to give a Pd(IV) complex (see D in Scheme 4). ${ }^{14}$ This complex would then undergo a reductive elimination, to give $\mathbf{E}$, followed by a symmetrization process, leading to $\mathbf{6}$ or $\mathbf{7}$ and $\operatorname{PdX}_{2}$. A $\operatorname{Pd}(I I)$ complex similar to the proposed intermediate $\mathbf{E}$ has been reported by Espinet et al. ${ }^{50}$ Pure palladium bromide or palladium iodide was quantitatively isolated from the reaction mixture by filtration, as a dark brown solid. It is interesting to note that, when $I_{2}$ is used as oxidative agent, only $\mathrm{PdI}_{2}$ and the dibromo complex 7 are formed. These solids were then reacted with $\mathrm{PPh}_{3}(1: 2)$ to give $\left[\mathrm{PdBr}_{2}\left(\mathrm{PPh}_{3}\right)_{2}\right]$ or $\left[\mathrm{PdI}_{2}\left(\mathrm{PPh}_{3}\right)_{2}\right]$, which were characterized by ${ }^{31} \mathrm{P}$ NMR.

Scheme 4. Proposed reaction pathway for the synthesis of 2-halo derivatives of phenylalanine methyl ester $\mathbf{8}$ and $\mathbf{9}$.
(S)-2-Bromo-phenylalanine methyl ester (8) and (S)-2-iodo-phenylalanine methyl ester (9) were conveniently prepared by reacting the corresponding precursor (6 or 7) with 1,10-phenanthroline (phen). The iodo derivatives 7 and $\mathbf{8}$ decompose slowly at room temperature. The by-product in these reactions, $\left[\operatorname{PdBr}_{2}(\mathrm{phen})\right]$, precipitates from the reaction mixtures and can be easily separated from the final amines by filtration (Scheme 4). Curiously, an analogous complex, $\left[\mathrm{PdCl}_{2}(\mathrm{phen})\right]$, has been reacted with various aminoacids in the presence of a base to prepare palladium(II) N,O-chelated amino acidato complexes with cytotoxic activity. ${ }^{16}$

Substitution of the Pd atom by bromine or iodine was confirmed by ${ }^{13} \mathrm{C}$ NMR spectroscopy. The resonance due to the aromatic carbon atom bonded to Br or $\mathrm{I}(\delta=124.7, \mathbf{8}$; $100.8,9$ ) is shifted to lower frequency with respect to the corresponding signals in the cyclometalated complex 1b $(\delta=140.8)$ and in the free ligand $(\delta=129.3$, DMSO-d6). This is
a well-known effect. ${ }^{51}$ In addition, the ${ }^{1} \mathrm{H}$ NMR spectra of the 2-halo amino acid methyl esters 8 and 9 showed the signals corresponding to the $\mathrm{NH}_{2}$ groups shifted to lower frequency with respect to those of $\mathbf{6}$ and 7, as expected upon palladium de-coordination.

## Conclusions

Using the appropriate experimental conditions, L-phenylalanine methyl ester can be ortho-metalated. The crystal structure of the mononuclear complex containing 4-picoline has been determined by X-ray diffraction. The cyclopalladated compound is an excellent starting material to prepare, in a stereospecific form, functionalized derivatives of this amino acid, as tetrahydro isoquinolines and 2-halo phenylalanine methyl esters.

## Experimental Section

General procedures. Infrared spectra were recorded on a Perkin Elmer 16F-PC-FT spectrometer. $\mathrm{C}, \mathrm{H}$ and N analyses and melting point determinations were carried out as described elsewhere. ${ }^{9}$ Unless otherwise stated, NMR spectra were recorded in $\mathrm{CDCl}_{3}$ with Bruker Avance 300 or 400 spectrometers. Chemical shifts are referenced to TMS ( ${ }^{1} \mathrm{H}$ and $\left.{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}\right)$ or $\mathrm{H}_{3} \mathrm{PO}_{4}\left({ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}\right)$. Signals in the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of all complexes were assigned with the help of HSQC and HMBC techniques. FAB MS measurements were carried out from liquid samples using 3-nitrobenzyl alcohol as a matrix in a VG Autospec E apparatus. Chromatographic separations were carried out by TLC on silica gel 60 ACC (70230 mesh). Reactions were carried out at room temperature without special precautions against moisture. L-Phenylalanine methyl ester hydrochloride, 4-methylpyridine (4-picoline), 2,6-dimethylphenyl isocyanide (xylyl isocyanide), tert-butyl isocyanide, $\mathrm{PPh}_{3}$ (Fluka), 1,10-
phenanthroline monohydrate, (Merck) and palladium acetate (Johnson Matthey) were used as received. $\mathrm{TlOTf}\left(\mathrm{TlSO}_{3} \mathrm{CF}_{3}\right)$ was prepared by reaction of $\mathrm{Tl}_{2} \mathrm{CO}_{3}$ and $\mathrm{HSO}_{3} \mathrm{CF}_{3}(1: 2)$ in water and recrystallized from acetone $/ \mathrm{Et}_{2} \mathrm{O}$.

Caution! Special precautions should be taken in handling thallium(I) compounds because of their toxicity.

## Synthesis of $(S, S)-\left[P_{2}\left\{\kappa^{2}-C, N-C_{6} H_{4} \mathrm{CH}_{2} \mathbf{C H}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \mathrm{NH}_{2}-2\right\}_{2}(\mu-\mathrm{Br})_{2}\right]$ (1b). $L-$

 phenylalanine methyl ester hydrochloride ( $1.00 \mathrm{~g}, 4.64 \mathrm{mmol}$ ) was added to a solution of $\mathrm{Pd}(\mathrm{OAc})_{2}(1.04 \mathrm{~g}, 4.64 \mathrm{mmol})$ in acetonitrile $(60 \mathrm{~mL})$, and the resulting solution was stirred at room temperature for 6 days. A small amount of metallic palladium was formed. The mixture was filtered through a plug of $\mathrm{MgSO}_{4}$, the filtrate was concentrated to dryness, the residue dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(5 \mathrm{~mL})$ and $\mathrm{Et}_{2} \mathrm{O}(30 \mathrm{~mL})$ was added to precipitate an orange solid which was filtered, washed with $\mathrm{Et}_{2} \mathrm{O}(2 \times 2 \mathrm{~mL})$ and air-dried $(1.26 \mathrm{~g}) .{ }^{1} \mathrm{H}$ NMR of this solid in $\mathrm{CDCl}_{3}$ shows very broad peaks, difficult to assign, but the analysis of the aromatic region indicates $a$ mixture $1: 0.35$ of the ortho-metalated complex $\quad\left[\mathrm{Pd}_{2}\left\{\kappa^{2}-C, N-\right.\right.$ $\left.\left.\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{2} \mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \mathrm{NH}_{2}-2\right\}_{2}(\mu-\mathrm{Cl})_{2}\right]$ and other non-ortho-metalated species such as $\left[\mathrm{Pd}_{2}(\mu-\right.$ $\left.\mathrm{Cl}) \mathrm{Cl}\left\{\mathrm{NH}_{2} \mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \mathrm{CH}_{2} \mathrm{Ph}\right\}_{2}\right]$ or $\left[\mathrm{Pd}_{2} \mathrm{Cl}_{2}\left\{\mathrm{NH}_{2} \mathrm{CH}\left(\mathrm{CO}_{2} \mathrm{Me}\right) \mathrm{CH}_{2} \mathrm{Ph}\right\}_{2}\right]$. This mixture $\mathbf{A}$ could not be separated neither by fractional crystallization nor by chromatography. To a solution of mixture $\mathbf{A}(950 \mathrm{mg})$ in acetone $(50 \mathrm{~mL}), \mathrm{NaBr}(1.5 \mathrm{~g}, 19.4 \mathrm{mmol})$ was added. The reaction mixture was stirred for 12 h and acetone was evaporated. The residue was taken in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(30 \mathrm{~mL})$, the suspension filtered through a plug of $\mathrm{MgSO}_{4}$, the filtrate was concentrated to dryness, and $\mathrm{Et}_{2} \mathrm{O}(30 \mathrm{~mL})$ was added. The orange solid obtained was filtered, washed with $\mathrm{Et}_{2} \mathrm{O}(2 \times 2 \mathrm{~mL})$ and air-dried to afford crude complex 1b. Yield: $631 \mathrm{mg}, 0.866$ $\mathrm{mmol}, 49 \%$. An analytically pure sample of complex $\mathbf{1 b}$ was obtained by recrystallization of $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{Et}_{2} \mathrm{O} . \mathrm{Mp}: 147{ }^{\circ} \mathrm{C}$ dec. Anal. Calcd for $\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{Br}_{2} \mathrm{~N}_{2} \mathrm{O}_{4} \mathrm{Pd}_{2}$ (729.03): C, 32.95; H,3.32; N, 3.84. Found: C, 33.49; H, 3.54; N, 4.15. X-ray Structure Determinations. X-ray data for complexes 2, 4 and 5 are summarized in Table 1. Data Collection. Crystals were mounted in inert oil on a glass fiber and transferred to a Bruker SMART APEX diffractometer. Data were recorded at low temperature and using $\omega$ scans. Multiscan absorption corrections were applied. Structure Solution and Refinements. Structures were solved by the heavy-atom method (2) or by direct method (4, 5) and refined anisotropically on F2 using the program SHELX-97 (G. M. Sheldrick. University of Göttingen, Göttingen, Germany). Hydrogen atoms were refined as follows: $\mathrm{NH}_{2}$ and NH , free; methyl, rigid group; all others, riding.

Acknowledgment. We thank Ministerio de Educación y Ciencia (Spain) and FEDER (CTQ2004-05396) for financial support. J.-A. G.-L. and B. C.-C. are grateful to the Ministerio de Educación y Ciencia (Spain) for their research grants.

Supporting Information Available. Details (including symmetry operators) of hydrogen bondings and listing of all refined and calculated atomic coordinates, anisotropic
thermal parameters, bond lengths and angles and CIF files for complexes 2, $\mathbf{4}$ and 5. This material is available free of charge via the Internet at http://pubs.acs.org.
